Solve Differential Equation with Condition. In the previous solution, the constant $C1$ appears because no condition was specified. Solve the equation with the initial condition $y(0) == 2$. The dsolve function finds a value of $C1$ that satisfies the condition.

In mathematics, an ordinary differential equation (ODE) is a differential equation containing one or more functions of one independent variable and the derivatives of those functions. The term ordinary is used in contrast with the term partial differential equation which may be with respect to more than one independent variable.

In mathematics, a differential equation is an equation that relates one or more functions and their derivatives. In applications, the functions generally represent physical quantities, the derivatives represent their rates of change, and the differential equation defines a relationship between the two.

We don't know values for the parameters b and k yet, but we can estimate them, and then adjust them as necessary to fit the excess death data. We have already estimated the average period of infectiousness at three days, so that would suggest $k = 1/3$. If we guess that each infected would make a possibly infecting contact every two days, then b would be $1/2$.

A differential equation is an equation which contains one or more terms which involve the derivatives of one variable (i.e., dependent variable) with respect to the other variable (i.e., independent variable). $dy/dx = f(x)$ Here "x" is an independent variable and "y" is a dependent variable. For example, $dy/dx = 5x$. A differential equation that contains derivatives which are either ...
