Natural selection occurs when individuals have different chances of survival and reproduction based on their inherited traits. This simulation explores the survival of

prey species individuals based on their coloring and the environment. The user controls the predator in the simulation and "eats" the prey by clicking on them.

Evolution is established by a process called Natural Selection, which is the process which organisms in a population that have physical or behavioral traits that better suited

to their current environment are more likely to survive, and to reproduce than individuals without traits less well suited to the current environment. Darwin stated that natural selection is process in five steps:

- Species produce sexually for more offspring

Natural selection Definition and Examples | Biology Online ...

Natural selection affects traits related to survival and producing offspring, while sexual selection specifically affects traits related to obtaining mates. Often traits that

increase an individual's access to mates, actually decreases their survival. One of the models in this section depicts this evolutionary trade-off.
