Superconductors have zero electrical resistivity, however semiconductors have finite resistivity. There is an electron-electron attraction in superconductors which leads to the vanishing of resistivity, however electron-electron repulsion in Semiconductors leading to the finite resistivity of semiconductors.

In simple words, good conductors of electricity (such as copper) are called as conductors and non-conductors (such as paper) are called as insulators. There are some materials, which are not good conductors of electricity neither good insulators, such materials are called as semiconductors.

Semiconductors are those materials which are neither good conductors nor good insulators. Their conductivity is intermediate between conductors and insulators. Silicon and germanium are semiconductor elements, at room temperature. The conducting of semiconductors is charged by temperature applied voltage or incident light. Pure silicon or germanium are poor conductors but by doping with impurities change the conductivity a lot. The temperature coefficient of resistivity is negative for ...

Due to exchange of electrons - to achieve the noble gas configuration - semiconductors arrange as lattice structure. Unlike metals, the conductivity increases with increasing temperature. Increasing temperatures leads to broken bonds and free electrons are generated. At the location at which the electron was placed,...

Semiconductors, Insulators & Conductors, Basic Introduction, N type vs P type Semiconductor

Superconductivity is the set of physical properties observed in certain materials, wherein electrical resistance vanishes and from which magnetic flux fields are expelled. Any material exhibiting these properties is a superconductor. Unlike an ordinary metallic conductor, whose resistance decreases gradually as its temperature is lowered even down to near absolute zero, a superconductor has a characteristic critical temperature below which the resistance drops abruptly to zero. An electric curre
