*Equilibrium Solutions and Stability As our work in Activity  $\{\text{PageIndex}\{1\}\}$  demonstrates, first-order autonomous solutions may have solutions that are constant. In fact, these are quite easy to detect by inspecting the differential equation  $\{dy/dt = f(y)\}$ : constant solutions necessarily have a zero derivative so  $\{dy/dt = 0 = f(y)\}$ .*

*To find equilibrium solutions we set the differential equation equal to 0 and solve for  $y$ .  $0 = y^2 - y = y(y - 1)$  so the equilibrium solutions are  $y = 0$  and  $y = 1$ . Now to figure out if the other solutions are trying to snuggle up to or run away from each of these equilibrium solutions.*

*In mathematics, stability theory addresses the stability of solutions of differential equations and of trajectories of dynamical systems under small perturbations of initial conditions. The heat equation, for example, is a stable partial differential equation because small perturbations of initial data lead to small variations in temperature at a later time as a result of the maximum principle.*

### Equilibrium Solutions And Stability Differential

So, it looks like we've got two equilibrium solutions. Both  $(y = -2)$  and  $(y = 3)$  are equilibrium solutions. Below is the sketch of some integral curves for this differential equation. A sketch of the integral curves or direction fields can simplify the process of classifying the equilibrium solutions.
