To understand the answers to these questions, it helps to have a basic definition of a magnet. Magnets are objects that produce magnetic fields and attract metals like iron, nickel and cobalt. The magnetic field's lines of force exit the magnet from its north pole and enter its south pole. Permanent or hard magnets create their own magnetic field all the time.

However, a ferromagnetic material will still lose its magnetism if you heat it above a certain point, known as its Curie temperature. Iron has a Curie temperature of 770°C (1300°F), while for nickel the Curie temperature is -355°C (-670°F). If you heat an iron magnet to 800°C (-1500°F), it stops being a magnet.

A voltage tester, as the name suggests, is used for testing the presence of voltage in a circuit. A voltage tester has a neon bulb with two wires attached to its bottom. This is used to test the flow of current in a wire. A good voltage tester is rated for up to 500 V. In the old days, Phase Tester also were used for this purpose. Related Posts:

Magnetism is a property of materials that makes them experience a force in a magnetic field. But what makes a metal magnetic? It is all down to unpaired electrons: moving electrons create magnetism due to their magnetic charge, but in most atoms electrons are paired and so cancel each other out. Most people know the basics of magnets:

Gases: Oxygen and nitrogen are naturally-occurring gases. Together, they make up most of the air we breathe. Hydrogen is the most common naturally-occurring gas in the universe.; Liquids: Perhaps the most important naturally-occurring liquid in the universe is water. Made up of hydrogen and oxygen, water behaves differently from most other liquids because it expands when frozen.
