Introduction. The group delay and phase delay properties of a linear time-invariant (LTI) system are functions of frequency, giving the time from when a frequency component of a time varying physical quantity—for example a voltage signal—appears at the LTI system input, to the time when a copy of that same frequency component—perhaps of a different physical phenomenon—appears at the ...

For a causal discrete-time FIR filter of order N, each value of the output sequence is a weighted sum of the most recent input values: $y[n] = \sum_{k=0}^N x[n-k] w_k$, where: $x[n]$ is the input signal, $y[n]$ is the output signal, N is the filter order; an N -order filter has $N+1$ terms on the right-hand side; w_k is the value of the impulse response at the k 'th instant for of an N -order FIR filter.

The input signal to a unity-gain second-order lowpass Butterworth filter is a full-wave rectified sine wave with an amplitude of 2.5n V and a fundamental frequency of 5000 rad/s. The corner frequency of the filter is 1 krad/s. Write the first two terms in the Fourier series that represents the steady-state output voltage of the filter.
