The term bed load or bedload describes particles in a flowing fluid (usually water) that are transported along the bed. Bed load is complementary to suspended load and wash load.. Bed load moves by rolling, sliding, and/or saltating (hopping).. Generally, bed load downstream will be smaller and more rounded than bed load upstream (a process known as downstream fining).

==>> For more on Mixtures (Solutions, Suspensions, Emulsions, Colloids) In summary: A solution is always transparent, light passes through with no scattering from solute particles which are molecule in size. The solution is homogeneous and does not settle out. A solution cannot be filtered but can be separated using the process of distillation.

Solutions, Suspensions and Emulsions
Liquid mixtures can be divided into 4 main types : solutions, suspensions, colloids and emulsions
Solutions
:-consist of soluble material or material (solute) dissolved in a liquid (solvent)-are clear-are homogenous (one phase) and do not settle

Dispersions

The movement of loose sediment by bedload and suspension loads in flowing water and air. This is part of the How To...series on physical sedimentology. Movement of sediment creates beds, structures within beds (e.g. laminations, crossbedding), and entire depositional systems like deltas and submarine fans.

The key difference between solution and suspension is that the particles of a solution are invisible to the naked eye whereas the particles of the suspension are visible.. In the natural environment, most of the substances exist as mixtures (E.g. air, water). In a mixture, there are two or more substances, but they do not join with each other by chemical means.

Types of Sediment Transport - Sahra
The suspension is a heterogeneous mixture in which the solute particles do not dissolve but get suspended throughout the bulk of the medium. Suspensions of stabilized, uniformly sized particles exhibit many of the phases are seen in pure atomic or molecular systems.

Sediment transport - Wikipedia
' Water moving through the drainage basin can convey material in solution (as solutes), or mechanical particles in suspension (suspended sediment) or by being rolled or jumped along the bed of a river as bedload. '

Sediment transport is the movement of solid particles (), typically due to a combination of gravity acting on the sediment, and/or the movement of the fluid in which the sediment is entrained. Sediment transport occurs in natural systems where the particles are clastic rocks (sand, gravel, boulders, etc.), mud, or clay; the fluid is air, water, or ice; and the force of gravity acts to move the ...
