2.1 -The Lumped Element Circuit Model for Transmission Lines

The transmission line theory, works in conditions where the transmission line is equal to a part of the signal wavelength. ... And this circuit is called lumped elements circuit. The transmission line always has at least two conductors and is schematically presented with a two-wire line.

The majority of modern distributed-element circuits use planar transmission lines, especially those in mass-produced consumer items. There are several forms of planar line, but the kind known as microstrip is the most common. It can be manufactured by the same process as printed circuit boards

Transmission Lines and Lumped Circuits: Fundamentals and ...

The generalized lumped-element model of a transmission line can be used to calculate characteristic impedance, phase velocity, and both parts of the propagation constant (phase and attenuation). The model uses an infinitesimally small section of a transmission line with four elements as shown below.

If the circuit in question handles low-frequency AC power, such short time delays introduced by a transmission line between when the AC source outputs a voltage peak and when the source “sees” that peak loaded by the terminating impedance (round-trip time for the incident wave to reach the line’s end and reflect back to the source) are of little consequence.

Transmission Line Model - Microwaves101

Abstract: Necessary and sufficient conditions are derived for a function to be the driving-point impedance of a physically realizable network consisting (essentially) of lumped resistors and lossless transmission lines. The circuits so developed are thoroughly practical for pure reactances and in many other special cases, but, in general, ideal transformers are sometimes required.

Physically separate elements such as resistors, inductors, capacitors & those elements whose net effect of electrical phenomenon in a circuit can be described in term of its terminal voltage and current (which are a function of time and does not depend on the change in position of the elements), are lumped elements. In a transmission line, these elements (resistors, inductors and capacitors) are distributed across the entire length of the transmission circuit (called as distributed

Transmission Lines And Lumped Circuits

The time-domain analysis of networks composed of linear transmission lines and nonlinear and/or time-varying lumped circuits is at the basis of design and verification of modern high-speed electronic circuits and large power distribution systems. This book provides an in-depth and comprehensive study of time-domain models of these networks.

Depending on circuit sensitivity, the distributed model for transmission lines starts deviating from the simplified lumped element model between line length of $0.01x$ and $0.1x$ the wavelength of the signal. This simulation uses a load impedance that is close to the impedance of the transmission line, so the reflections are relatively small.

A network consisting of an ideal two-conductor line connecting two lumped circuits is considered in the chapter. The two-port representing the ideal two-conductor transmission line is directly characterized in the time domain. Both an input–output description and an input–state–output description are thoroughly investigated.
